

The carrot is alive when you peel it

Plants have a far greater number of certain sense receptors compared to animals and humans and wide-ranging processes are activated when plants need to react on external signals.

When you open the refrigerator door, carrots, onions and cucumbers sense it and a thousand life processes are started in the hope that the long winter's night is now over. The shadow from your hand is immediately sensed, as is the firm grip that immediately starts off signalling processes. Their purpose is to interpret what is happening and how to respond aptly to the new situation.

When the carrot is peeled, it's alive. And each of the fragmented carrot shavings from the shredder is alive for many hours after attack and works overtime to find solutions to the impossible situation.
